

### 1. Matrix Derivation:

$$f: R^n \rightarrow R$$

$$\frac{\partial f(x)}{\partial x} = \begin{pmatrix} \frac{\partial f}{\partial x_1} \\ \frac{\partial f}{\partial x_2} \\ \dots \\ \frac{\partial f}{\partial x_n} \end{pmatrix} \in R^n$$

$$f: R^{m \times n} \rightarrow R$$

$$\frac{\partial f(x)}{\partial x} = \begin{pmatrix} \frac{\partial f}{\partial x_{11}} & \frac{\partial f}{\partial x_{12}} & \dots & \frac{\partial f}{\partial x_{1n}} \\ \frac{\partial f}{\partial x_{m1}} & \frac{\partial f}{\partial x_{m2}} & \dots & \frac{\partial f}{\partial x_{mn}} \end{pmatrix} \in R^{m \times n}$$

### 2. Convex:

$$J(\alpha\theta_1 + (1-\alpha)\theta_2) \leq \alpha J(\theta_1) + (1-\alpha)J(\theta_2)$$

$$\text{or in } R, J''(\theta) \geq 0, \forall \theta$$

### 3. Linear Regression:

$$\hat{\theta} = \arg \min_{\theta} \sum_i l(\theta^T \phi(x_i), y_i), l \text{ is } l_2\text{-norm}^2$$

$$\hat{\theta} = \arg \min_{\theta} \sum_i \|\theta^T \phi(x_i) - y_i\|_2^2$$

$$\text{Convex, let Derivative} = 0 \Rightarrow \frac{\partial J(\theta)}{\partial \theta} = 0$$

$$\sum_i 2(\theta^T \phi(x_i) - y_i) \phi(x_i) = 0 \Rightarrow \Phi^T \Phi \theta = \Phi^T Y$$

$$\text{Cost time: } O(d^3 + d^2 N) \text{ When not invertible: } n < d$$

since  $rk(\Phi^T \Phi) < rk(\Phi) < \min\{n, d\}$ , when  $n < d$  we have  $rk(\Phi^T \Phi) = n < d$  then it is not-full rank.

#### Deal with Outliers:

- remove detected Outliers
- Robust Regression function: Huber loss Func. We write  $\phi(x_i) - y_i$  as  $e$ , where  $\delta$  is a hyperparameter MSE squares errors, outliers will distort the loss value significantly. Huber loss calculate  $l_1$  norm on large values which gives more tolerance.

$$l_{\delta}(e) = \begin{cases} \frac{1}{2}e^2 & |e| \leq \delta \\ \delta|e| - \frac{\delta^2}{2} & |e| \geq \delta \end{cases}$$

$$\frac{\partial l_{\delta}(e)}{\partial e} = \begin{cases} e & -\delta \leq e \leq \delta \\ \delta & e > \delta \\ -\delta & e < -\delta \end{cases}$$

#### Deal with Overfitting: overfitting might have large $\theta$

$$\arg \min_{\theta} \sum_{i=1}^N (\theta^T \phi(x_i) - y_i)^2 + \lambda \|\theta\|_2^2$$

$$\text{Closed Form: } (\Phi^T \Phi + \lambda I_d) \theta = \Phi^T Y$$

$$\lambda \rightarrow 0 \text{ same as original; } \lambda \rightarrow \infty, \hat{\theta} \rightarrow \vec{0}$$

When selecting  $\lambda$ , the naive training on all data is not work since  $\lambda = 0$  minimizes the overall error.

- We need to Train  $\lambda_i$  on **training set** to minimize the cost function
- Measure error on the **hold-out set**  $D^{ho}$  and find the  $\lambda$  that minimize  $\epsilon^{ho} = \sum_{x_i, y_i \in D^{ho}} (y_i - (\theta_{\lambda}^*)^T x_i)^2$

### 4. Gradient Descent:

$$\text{Start with } \theta^{(0)} \in R^d$$

$$\text{In each iteration, update } \theta \text{ until } \|\theta^{(k)} - \theta^{(k+1)}\| < \epsilon$$

$$\theta^{(k+1)} = \theta^{(k)} - \rho \frac{\partial J(\theta)}{\partial \theta} \Big|_{\theta^{(k)}}$$

$O(Nd)$  in each iteration.

Stochastic gradient descent: randomly select 1 data entry when computing derivative in each iteration.

### 5. K-fold cross validation

divide Data set to k equally large sets  $\{D_1, D_2, \dots, D_k\} \in D$

- For  $\lambda \in \{\lambda_1, \lambda_2, \dots, \lambda_p\}$ 
  - For  $i = 1, 2, \dots, k$ 
    - \* train on  $\bigcup_{j \neq i} D^j$  and get  $\theta_i^*(\lambda)$
    - \* compute validate error on  $D^i \rightarrow \epsilon_i^{ho}(\lambda)$
    - compute average of  $\{\epsilon_i^{ho}(\lambda)\}$ :  $\epsilon^{ho} = \frac{1}{k} \sum_{i=1}^k \epsilon^{ho}(\lambda)$
- select  $\lambda^* = \min_{\{\lambda_1, \lambda_2, \dots, \lambda_p\}} \epsilon^{ho}(\lambda)$

### 6. Probability review:

$$\text{Condition: } P(X|Y) = \frac{P(X,Y)}{P(Y)} \Leftrightarrow P(X,Y) = P(X|Y)P(Y)$$

$$\text{Bayes law: } P(X|Y)P(Y) = P(Y|X)P(X)$$

$$\text{Chain rule of Probability: } P(x_1, x_2, \dots, x_n) = p(x_1)p(x_2|x_1)p(x_3|x_1, x_2) \dots P(x_n|x_1, \dots, x_{n-1}) \text{ Independent: } P(X,Y) = P(X)P(Y)$$

$$\text{Expectation: } E(f(X)) = \sum f(x)p(x) \text{ or } \int f(x)p(x)dx$$

$$\text{Given } X \perp\!\!\!\perp Y, E[XY] = E[X]E[Y]$$

iid r.v: independent and identically destributed

### 7. Maximum Likelihood Estimation (MLE):

$\theta^* = \arg \max_{\theta} P_{\theta}(D)$  Under such  $\theta^*$ , probability of observing the given dataset is maximum.  $L(\theta) = P(D|\theta) = \prod P(x_i)$ , maximize  $L(\theta)$ . Solve:  $\frac{\partial \log(L(\theta))}{\partial \theta}$

### 8. Logistic Regression:

$w\phi(x) > 0 \Rightarrow g(x) = 1, w\phi(x) \leq 0 \Rightarrow g(x) = 0$  Then, we have the model:

$$P(y = 1|x) = \delta(w^T \phi(x)) = \frac{1}{1 + e^{-w^T \phi(x)}}$$

#### Training:

$$\text{Train through MLE } \max_w P_w(D) = \max_w P_w(y_1|x_1) \dots P_w(y_N|x_N)$$

$$\text{We can write: } P_w(y_i|x_i) = P_w(y_i = 1|x_i)^{y_i} P_w(y_i = 0|x_i)^{1-y_i}$$

$$L(w) = \log P_w(D) = \sum_{i=1}^N \log\left(\frac{1}{1+e^{-w^T \phi(x_i)}}\right)^{y_i} + \log\left(\frac{1}{1+e^{w^T \phi(x_i)}}\right)^{1-y_i}$$

$$= \sum_{i=1}^N (y_i w^T \phi(x_i)) - \log(1 + e^{w^T \phi(x_i)})$$

equivalent to minimize  $-L(w)$

$$\Rightarrow \arg \min_w J(w) \sum_{i=1}^N [-y_i w^T \phi(x_i) + \log(1 + e^{w^T \phi(x_i)})] \text{ take}$$

$$\text{derivative: } \frac{\partial J(w)}{\partial w} = \sum_{i=1}^N -y_i \phi(x_i) + \phi(x_i) \frac{1}{1 + e^{-w^T \phi(x_i)}}$$

No closed form, use GD.

#### Deal with overfitting:

Do regularization on  $w$ .

$$\min_w \tilde{J}(w) = J(w) + \frac{\lambda}{2} \|w\|_2^2$$

$$\text{In GD, it is just } \frac{\partial \tilde{J}(w)}{\partial w} = \sum_{i=1}^N \phi(x_i)(-y_i + \frac{1}{1 + e^{-w^T \phi(x_i)}}) + \lambda w$$
